

ABSTRACT

A lamp assembly 10 has a light source 12 having two sealed electrodes 14, 16, sealed in a
5 seal area 17 and defining a lamp axis 18. A concave shell 20 has an internal surface 22 with
a reflective surface 23 formed thereon. The concave shell 20 has a neck 24 defining a neck
cavity 26 and a reflector axis 28. The neck 24 is provided with an electrical connection 30
and a mechanical support for the light source 12. The shell 20 surrounds the source 12 to
reflect light from the source 12 to a field to be illuminated during lamp operation. The
10 source 12 and the reflector surface 23 are oriented with the lamp axis 18 substantially co-axial
with the reflector axis 28, and at least a portion of at least one of the electrodes, for example,
14, extends into the neck cavity 26. A zone 32 is formed in the neck cavity 26 for
substantially redirecting specular reflection away from the seal area.
